6.5 Wine Quality Logistic Regression

This section explores feature selection based on regularization.

6.5.1 Regularized Logistic Regression with Spark

We now revisit the Wine Quality Data Set analyzed in Section 6.4.2. Our goal is to continue with advanced analyses.

We read the winequality-red.csv file into a Spark DataFrame using spark_red_csv. We want to ensure the training and test data frames are identical to those in Section 6.4.2.

```
wine_red_sdf <- spark_read_csv(sc, "wine_red_sdf",
    path = "file:///home/rstudio/rspark-tutorial/data/wine/winequality-red.csv",
    delimiter = ";" )
wine_red_tbl <- sdf_register(wine_red_sdf, name = "wine_red_tbl")</pre>
```

We split wine_red_sdf into a training and a test Spark DataFrame as before and cast quality as numeric in order to binarize it with a threshold.

The full model is now run on the training data.

```
## Coefficients:
```

```
##
           (Intercept)
                             fixed_acidity
                                               volatile_acidity
##
           0.085355662
                               0.037695073
                                                  -2.716727205
##
           citric acid
                            residual sugar
                                                     chlorides
           0.146470731
                               0.032588021
                                                   -6.506974957
##
   free_sulfur_dioxide total_sulfur_dioxide
##
                                                       density
##
           0.003297656 -0.013509022
                                                  -11.989654183
##
                                 sulphates
                                                       alcohol
                   рΗ
           0.989218532
                               2.614878613
##
                                                   0.882637121
```

The coefficients and AUC can be extracted from the ml_model object by:

```
wine_red_br_full_model$coefficients
##
            (Intercept)
                                fixed_acidity

However, it is preferable to use an evaluator, in this case ml_binary_classification_evaluator, to com-
pute the performance metrics.
wine_red_br_full_predict <- ml_predict(wine_red_br_full_model, wine_red_train_sdf)
wine_red_br_auc <- data.frame(lambda = 0,
                               auc = ml_binary_classification_evaluator(wine_red_br_full_predict))
wine_red_br_coef <- as.data.frame(wine_red_br_full_model$coefficients[-1])</pre>
wine_red_br_coef
##
                         wine_red_br_full_model$coefficients[-1]
## fixed_acidity
                                                      0.037695073
                                                     -2.716727205
## volatile_acidity
                                                      0.146470731
## citric_acid
## residual_sugar
                                                      0.032588021
## chlorides
                                                     -6.506974957
## free_sulfur_dioxide
                                                      0.003297656
## total sulfur dioxide
                                                     -0.013509022
## density
                                                    -11.989654183
## pH
                                                      0.989218532
## sulphates
                                                      2.614878613
## alcohol
                                                      0.882637121
Next we define a model function with the reg_param as an argument.
wine red br model <- function(1) {
  wine_red_train_sdf %>%
    ml_logistic_regression(quality_bin ~ fixed_acidity + volatile_acidity
                            + citric_acid + residual_sugar + chlorides
                            + free_sulfur_dioxide + total_sulfur_dioxide
                            + density + pH + sulphates + alcohol,
                            elastic_net_param = 1, reg_param = 1)
}
```

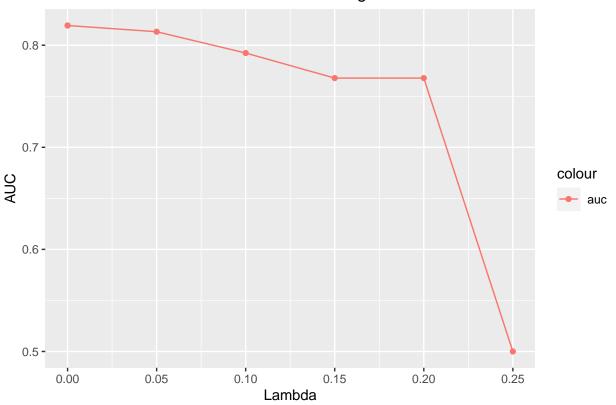

We are dealing with a lasso since the elastic net param is 1.

We now calculate the coefficients and auc for each of the models.

```
reg_parm \leftarrow c(0.0, 0.05, 0.1, 0.15, 0.2, 0.25)
for(l in reg_parm) {
```

```
wine_red_br_fit <- wine_red_br_model(1)</pre>
  wine_red_br_predict <- ml_predict(wine_red_br_fit, wine_red_train_sdf)</pre>
  wine_red_br_auc <- data.frame(lambda = 1,</pre>
                        auc = ml_binary_classification_evaluator(wine_red_br_predict)) %>%
    rbind(wine_red_br_auc, .)
  wine_red_br_coef <-
    as.data.frame(wine_red_br_fit$model$coefficients) %>%
    cbind(wine_red_br_coef, .)
}
wine_red_br_auc
##
    lambda
                  auc
## 1 0.00 0.8192924
## 2 0.00 0.8192924
## 3 0.05 0.8132053
## 4 0.10 0.7923273
## 5 0.15 0.7677938
## 6 0.20 0.7677938
## 7 0.25 0.5000000
We plot AUC, the chosen performance metric, against \lambda.
library(ggplot2)
wine_red_br_auc %>%
  ggplot(aes(x = lambda)) +
  geom_point(aes(y = auc, color = 'auc')) +
  geom_line(aes(y = auc, color = 'auc')) +
  ggtitle("Performance Metric for the Red Wine Regulated Models") +
  xlab("Lambda") + ylab("AUC")
```

Performance Metric for the Red Wine Regulated Models

The AUC decreases with λ and thus little if any regularization should be done.

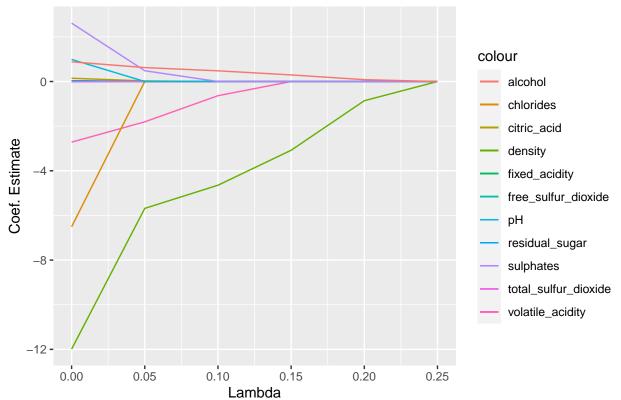

```
names(wine_red_br_coef) <- as.character(rbind(c(0.0, reg_parm)))
wine_red_br_coef</pre>
```

```

  geom_line(aes(y = total_sulfur_dioxide, color = 'total_sulfur_dioxide')) +
  geom line(aes(y = density, color = 'density')) +
  geom_line(aes(y = pH, color = 'pH')) +
  geom_line(aes(y = sulphates, color = 'sulphates')) +
  geom_line(aes(y = alcohol, color = 'alcohol')) +
  ggtitle("Parameter Trace for the Red Wine Regulated Models") +
  xlab("Lambda") + ylab("Coef. Estimate")
```

Parameter Trace for the Red Wine Regulated Models

The coefficients go to 0 very quickly. Based on regularization, alcohol and density are still standing at $\lambda = 0.2$, but then they too go to 0. However, for $\lambda > 0$ the AUC is degraded.

We now collect the training and test Spark DataFrames into R as regular data frames. If you experiment with alpha and lambda,i.e., invoke the elastic net, you will see the coefficients that are driven to 0 vary greatly.

```
wine_red_train_df <- collect(wine_red_partition$training)
wine_red_test_df <- collect(wine_red_partition$test)</pre>
```

6.5.2 Regularized Logistic Regression with glmnet

We can now use glmnet to model the wine quality.

```
wine_red.x <- model.matrix(as.factor(quality_bin) ~ fixed_acidity</pre>
                           + volatile_acidity + citric_acid + residual_sugar
                           + chlorides + free_sulfur_dioxide
                           + total_sulfur_dioxide + density + pH + sulphates
                           + alcohol,
                           data = wine_red_train_df)[, -1]
wine_red.y <- wine_red_train_df$quality_bin</pre>
wine red bin <- glmnet(x = wine red.x, y = wine red.y, family = "binomial",

```

Based on feature importance, alcohol, was indeed most important. You can experiment with different values of alpha and lambda.

[1] 0

glmnet confirms that no regularization is needed and thus no variable selection is done. At this point it is not clear how to proceed since the standard errors of the coefficient estimates are not available and thus testing is not possible.

Since we do not have a well-determined final model, we will not compute predictions or performance metrics on the test data set. Of course glm in base R was used in Section 6.4.2. pH, density, and residual_sugars were removed using AIC as a criterion, but further analysis is needed. ml_generalized_linear_regression does provide information on the AIC and thus could also be used for variable selection as was done in Section 6.4.2.
